#### **Abstract**

The Space Shuttle Main Engine (SSME) is a very complex power plant and plays a crucial role in Shuttle missions. To evaluate SSME performanace 1200 hot-fire ground tests have been conducted, varying in duration from 0 to 500 secs. During the test about 500 sensors are sampled every 20ms to measure the various parameters. The sensors are generally bounded by 'red-lines' so that an excursion beyond the red-line could lead to premature shutdown by the operator. In 27 tests, guided by the red-lines, it was not possible to effect an orderly premature shutdown. These tests became major incidents where serious damage to the SSME and the test stand resulted. In this study we have investigated the application of pattern recognition techniques to detect SSME performance trends that lead to major incidents. Based on the sensor data a set of (n) features is defined. At any time, during the test, the state of the SSME is given by a point in the n-dimensional feature-space. The entire history of a given test can now be represented as a trajectory in the n-dimensional feature of the 'normal' trajectories and the failed test space. Portions trajectories would lie in different regions of the n-dimensional feature space. The feature space can now be partitioned into regions of normal-tests and failed tests. In this manner it is possible to examine the trajectory of a test in progress and predict if it is heading into the 'normal-region' or the 'failure-region' of the n-dimensional feature space. In this study we have developed techniques to extract features from ground test data, as supplied by Rocketdyne, and develop feature space trajectories for the tests. The initial results as presented here, look very promising.

#### Introduction

The Space Shuttle Main Engine (SSME) based on Hydrogen-Oxygen combustion is a very complex power plant employing numerous pumps, valves and ducts as shown in Fig.1. During a ground test about 500 sensors are used to monitor the state of SSME. Some of these sensors are used for the close loop control of SSME and are connected to a Computer System 'Engine Controller' as shown in Fig.2.

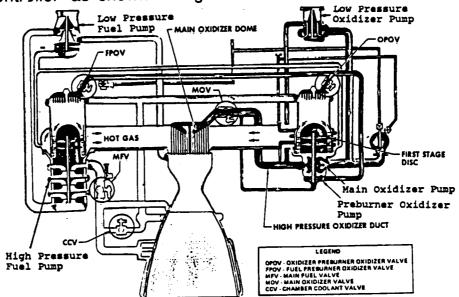

Fig. 1 SSME Propellant Flow Schematic

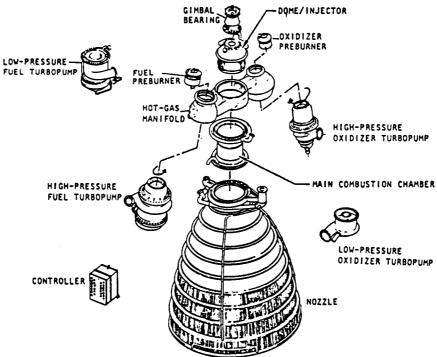

Fig. 2 Engine Controller & Hot Gas Manifold

There are 3 different data acquisition systems used to collect the sensor data (1,2), namely,

- -- Command and Data Simulator (CADS)
- -- Facility Recording (FR), and
- -- Analog High Frequency Recording (AHFR)

In Fig. 3, the salient points of these systems is shown. The engine controller uses 16 bit computations on 12-bit data words to perform close loop operation of the SSME. For the SSME Anomaly and Failure Detection (SAFD) analysis, as reported in (2), the CADS and FR data provide the bulk of the input.

In all about 1200 hot fire tests have been conducted on the SSME. In 27 tests the SSME went out of control and serious damage to the engine and the teststand resulted. A summary of some of the salient points of the ground tests is given in Table 1.

Considering that the replacement cost of an engine is ~\$50M, it is highly desirable to develop some technique for detecting failure trends which would allow an orderly shutdown of the SSME and thereby preventing a major incident (3). In (2) and (3) various techniques for failure detection have been suggested including the following,

- -- Generalized Likelihood Ratio (GLR)
- -- Generalized Likelihood Test (GLT)
- -- Voting
- -- Confidence Region Tests
- -- Kalman Filters
- -- Parameter Estimation
- -- Jump Processes
- -- Pattern Recognition.

The success of a technique will be determined by;

- -- detecting the fault fast enough to allow an orderly shutdown
- -- identifying the technical nature of the fault.

# SAFD Decision

SSME Status

Ideally, W1=W4=1 & W2=W3=0

## Fig. 4 SAFD performance matrix.

Note that W2 being the probability of a false alarm should be zero, however, a small value ,say 1%, may be acceptable. On the other hand W3 being the probability of a miss should indeed be zero, just as W4 should be 1. Various alternatives have been considered for implementing such a SAFD. We shall consider the use of Pattern Recognition (PR) techniques for SAFD. It should also be pointed out that much of the data processing in PR, as described below, can also be used for the other vital activities envisaged for the future systems, namely, real-time control, health assessment amd condition monitoring (4,5).

#### Pattern Recognition (PR)

The fundamental premise for applying PR techniques is the observation that when systems fail due to internal causes there are always some warning signs that preceed the event. Furthermore, the progression of a system from normal operating mode to anomalous (failure) mode does not happen at random but follows a pattern which can be analysed and explained. The object of PR technique, described here, is to identify the patterns that have led to failures and use this knowledge to look for warning signs in future tests and predict failures well in advance of their occurence.

The current practice is based on red-lining the sensor outputs. The red-lining of n-sensors can be easily explained in terms of a polyhedron in n-dimensions as shown in Figs. 5(a,b,c). Each sensor is assigned a lower-and an upper-bound value for 'normal' operation and these define the two 'red-lines' for that sensor. For a 3-sensor case the state of the system, at a given time, can uniquely be defined by a point in the rectangular prismatic region of the S1-S2-S3 Space (S-Space), Fig. 5c. The collection of these state-points at successive times would define a trajectory in the S-Space. All the possible normal runs of the system would then be given by trajectories that lie entirely within the 'red-lined' rectangular prism as shown in Fig. 6. In principle, any trajectory that tends to approach a boundary and exit to the outside region is an indication of an imminent failure.

One can learn to detect the failure trends by examining the data of the 27 tests that resulted in failure and compare it with the normal test data. It is quite possible that the failure trajectories will reveal their different character (as compared to normal trajectories) even before coming close to the red-line polyhedron boundary as shown in Fig. 7.

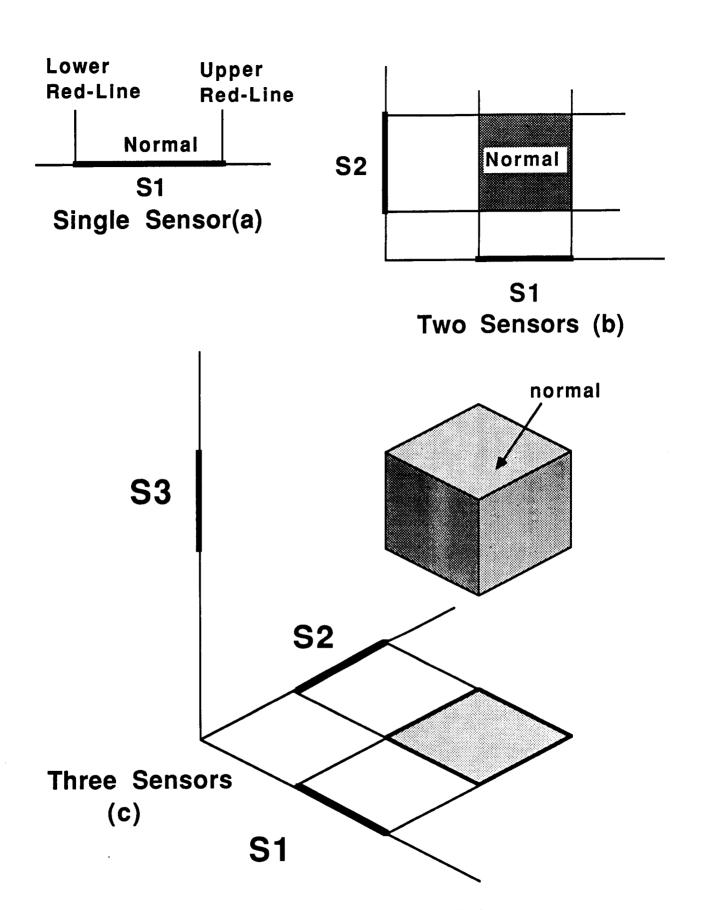

Fig. 5 Multi-Sensor Red-Lining

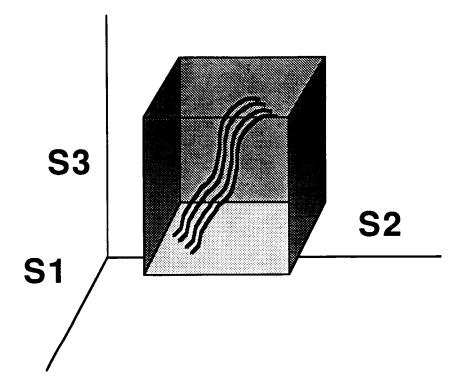

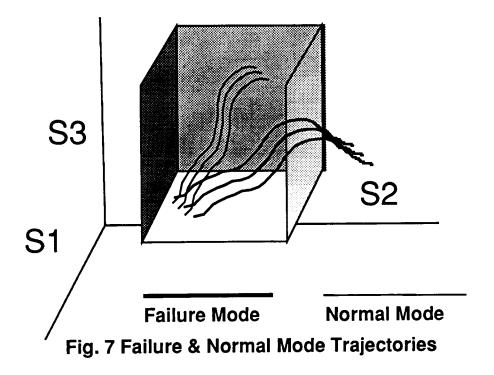

Fig. 6 System Trajectories in Sensor Space

There are two points that have to be considered in this context, namely,

1. The straight forward fixed red-lines for a sensor are adequate only for very special cases where no coupling among the sensors exists, i. e. the red-line for a given sensor is independent of the values of all the other parameters as measured by the rest of the sensors. Let  $r_k$  be the red-line for the kth sensor, then

$$r_k = c_k$$
, where c's are constants

The software red-lines can be defined by replaing c's by functions  $f_k$  so that,

$$r_k = f_k(S_1, S_2, \dots S_n)$$
, where  $S_k$  is the kth sensor reading

In real-time this implies that as the test is progressing the readings  $S_k$  are used to calculate the various  $r_k$ 's through  $f_k$ 's. This can become not only computationally quite cumbersome but the explicit form of  $f_k$  itself has to be known perhaps from a simulation model of the system. In principle, it is simple to build the simulation model in a modular manner (6), however, the ad hoc nature of such models leads to different control and real-time simulation models. By such models it is quite possible to determine most of the  $f_k$ 's, however, some crucial gaps may exist in this knowledge since not all the failure mechanisms are well understood.

2. Even if the  $f_k$ 's are known and the soft red-lines can be determined, there is yet another serious problem. In principle all red-lines, soft or otherwise, are based on a single time frame of the system without considering how the system got to the state represented by the time frame. Questions of the type; has the system reached its present state through a transient, slow drift, excessive noise or under a close-loop command etc., are not considered by red-line methods. The method proposed here considers the entire system trajectory and compares it with other trajectories to detect failure prone trajectories.

The PR technique we propose to employ here has two important steps,

- -- extension of the sensor-space into Feature Space
- -- Segmentation of the feature-space into normal- and failure-regions

#### Feature Space

The sensor space discussed above has two major drawbacks, namely,

-- For a truly multi-sensor system such as SSME the total amount of data is too large (about 100 Mbits) and can become too unwieldy for real-time processing.

On the other hand most of the data is of routine nature and a tremendous amount of data compression can be achieved by isolating and analysing only the deviations from the norm or the steady state. The norms can be defined as those values which can be calculated or predicted (assuming normal SSME operation) from a few key parameters e. g. power level, MCC pressure, throttle position etc. In the simplest case, only the deviations in sensor values, as compared to a moving average defined over a certain interval, are to be used for further analysis. This may even include deviations caused by closed- or open-loop control commands as may happen during throttling.

-- The sensor space, as based only on the sensor values, may not highlight the features important for SAFD.

This is based on the fact that the raw sensor readings, along with their red-lines, may themselves be not good indicators of impending failure. Further processing is often required to calculate features which are directly related to the failure modes. In Fig. 8 we show some of the features that can be defined for a given sensor. Starting with the raw value one can calculate first an average over a certain interval and then the deviation from it. From these one can also calculate the signal to noise ratio S/N which could be another feature. To detect drifts one can also calculate the local gradients as another feature. Similarly Fourier Transform of the signal (or the deviation), over a given time window, can be another feature, as shown in Fig. 8. One can also define 'compound' features involving data from more than one sensor. Thus, if needed, the net thermal flux, which may not be measured by a single sensor, can be calculated from the presure, flow velocity and temperature as measured by sensors in the MCC and it can be used as a feature for failure detection.

Based on the above discussion, the sensor space is replaced by a feature-time space, where a feature is defined as the deviation from the norm or steady-state as calculated from some key parameters or by averaging over a specified interval. The state of SSME, at any given time will thus be represented by a state point in the feature space. In Fig. 9 a normal SSME run is shown in a two-feature space. In a normal run, all the state points cluster around the time axis as shown, since no large deviations are encountered.

Fig. 8 Sensor Values & Features

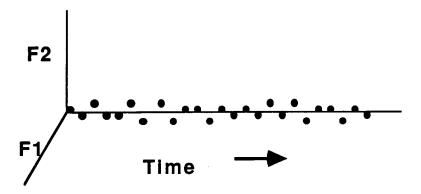

Fig. 9 Feature Space Representation of Normal SSME Test

#### Segmentation

Segmentation is the process of partitioning the feature space into clusters that can be identified with definite states of the system e. g. pre-failure or normal. An idealised illustration of this is shown in Fig.10 where the entire feature space has been projected along the time axis. All the points representing the normal runs should lie in a small region, cluster 1, around the origin. During normal runs there are large deviations caused by genuine excursions such as throttling etc. Such states of the system might show up as another region, cluster 2. It is anticipated that the deviations due to the failure modes will be of different nature and hopefully form another distinct region, cluster 3. An another form of the same situation is depicted in Fig.11 where an entire run is represented by a trajectory. A steady run trajectory would then lie entirely within cluster 1 whereas a controlled excursion in a run might cause the trajectory to migrate to cluste 2, but eventually return to cluster 1 after the steady state has been reached.

In practice, the situation may not be quite so clean cut, the clusters may not have so well defined boundaries and they may overlap. A number of powerful statistical techniques is available to locate cluster boundaries in such cases. It is also possible to assign to each state point, the probability of membership to a given cluster. One can also define a distance metric in the feature space to group points in clusters. In Table 2. (7) some of the commonly employed distance measures and the associated error bounds are shown.

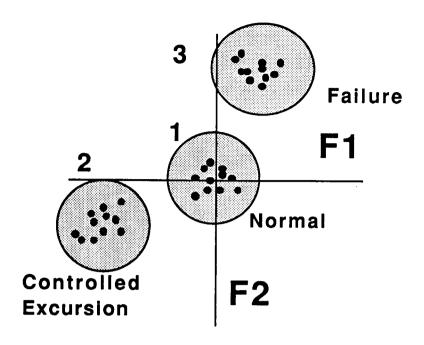

Fig. 10 Segmentation of the Feature Space

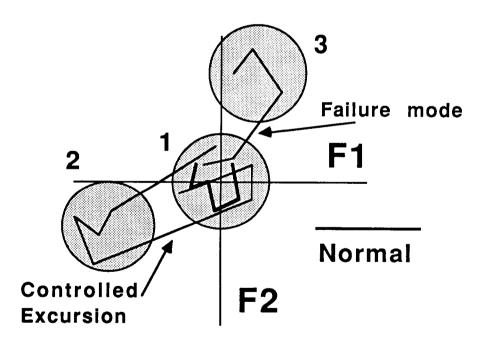

Fig. 11Trajectories across the Clusters

Table 2. Distance Measure and Error Bounds

Name	Expression	Relationships
Bayes error probability	$P_{\sigma} = 1 - \int_{S_{m-1}} \max_{i} \left[ P_{i} \rho(X w_{i}) \right] dx$	m Class Bounds
Equivocation or Shannon entropy	$H(\Omega X) = E\left\{-\sum_{i=1}^{m} P_{i}(w_{i} x) \log P_{i}(w_{i} x)\right\}$	$\frac{1}{2}[1 - B(\Omega X)]$ $\leq [1 - \sqrt{B(\Omega X)}] \leq \frac{m-1}{m} \left[1 - \sqrt{\frac{mB(\Omega X) - 1}{m-1}}\right]$
Average conditional quad- ratic entropy [Vajda (1970)]	$h(\Omega X) = E\left\{\sum_{i=1}^{m} P_r(w_i x)[1 - P_r(w_i x)]\right\}$	$\leq P_{\sigma} \leq \{1 - B(\Omega X)\}$
3) Bayesian distance [Devijver (1974)]	$B(\Omega X) = E\left\{\sum_{i=1}^{m} [P_i(w_i x)]^2\right\}$	$= h(\Omega X) = R_{\text{NN}} = \frac{m-1}{m} - M_0(\Omega X);$ $P_a \le \dots \le R_{\text{ENN}} \le \dots \le R_{\text{INN}} \le R_{\text{NN}}$
4) Minkowski measures of non- uniformity [Toussaint (1973)]	$M_k(\Omega X) = E\left\{\sum_{i=1}^{m} \left  P_r(w_i x) - \frac{1}{m} \right ^{2(k+1)/2k+1} \right\}$	[see Cover and Hart (1967) and Devijver (1974)]  Two Class Bounds
5) Bhattacharyya bound [see Kailath (1967)]	$b(\Omega X) = E\{[P_r(w_1 x) \cdot P_r(w_2 x)]^{1/2}\}$	multicategory error: $P_a \leq \sum_{i=1}^{m} \sum_{j=i+1}^{m} P_a(w_i, w_j)$ ;
6) Chernoff bound [see Kailath (1967)]	$C(\Omega X;s) = E([P_r(w_1 x)^{1-s} \cdot P_r(w_2 x)^r])$	$\frac{1}{2}(1-[J_{\epsilon}(\Omega X)]^{1/4}) \leq P_{\epsilon} \leq \frac{1}{2}(1-J_{\epsilon}(\Omega X)),  \text{for } x \geq 1$
7) Kolmogorov variational distance [see Kailath (1967)]	$K(\Omega X) = \frac{1}{2}E( P_r(w_1 x) - P_r(w_2 x) )$	upper bound equals $\{1 - B(\Omega X)\}$ , when $x = 2$ ; $Q_{a+1} \le Q_a; Q_0 = 1 - B(\Omega X);$
<ol> <li>Generalized Kolmogorov distance [Devijver (1974), Lissack and Fu (1973)]</li> </ol>	$J_{s}(\Omega X) = E( P_{r}(w_{1} x) - P_{r}(w_{2} x) ^{s}),  0 < x < \infty$	
9) A family of approximating functions [Ito (1972)]	$Q_{n}(\Omega X) = \frac{1}{2} - \frac{1}{2} [E\{[P_{n}(w_{1} X) - P_{n}(w_{2} X)]^{2(n+1)/2(n+1)}\}]$	
10) The Matusita distance [see Kailath (1967)]	$\gamma = \left[ \int_{S_n} \{ \rho(x w_1) - \rho(x w_2) \}^2 \ dx \right]^{1/2}$	7 gives the same bound as $b(\Omega X)$ ; two-class bound relations: $P_a \leq Q_a(\Omega X) \leq Q_0(\Omega X) \leq \frac{1}{2}H(\Omega X) \leq b(\Omega X)$ [see Ito (1972) and Hellman and Raviv (1970)]

Notation:  $\Omega = (w_i, i = 1, 2 \cdots m; 2 \le m < \infty)$ —a set of pattern classes;  $P_i$  is an a priori probability of class  $w_i$ ; X is a n dimensional vector random variable;  $S_x$  is a sample space of X;  $p(X|w_i)$  is a conditional probability density function;  $P_r(w_i|X)$  is a posterior probability of class  $w_i$  conditioned on X;  $f(X) = \sum_{i=1}^{m} P_i p(x_i|w_i)$ —the mixture distribution; E is an expectation over  $S_x$  with respect to f(X);  $R_{NN}$  is an m class infinite sample nearest-neighbor risk;  $R_{NN}$  is a k nearest-neighbor risk.

the steps employed in the above technique are;

- -- definition of the features and construction of the feature space
- -- plotting of ground test data (of both normal and failure tests) as trajectories in the feature space
- -- segmentation of trajectories into failure and normal runs.

Implementation of these steps in practice is discussed nelow.

#### Results and Conclusions

the data from a run is stored on a number of magnetic tapes. the data for a short interval (10-100 sec.) and from a few imortant ssrs is combined into a single tape file. This tape file is read into a disk file which can be accessed by application programs. Fig. 12 shows the header, or the Run-Log, of the disk data file. This data, as can be seen from the first line, is for the time period 320 to 392 secs. of the run #901-364 which resulted in a failure. It also shows the ssr PID#, the engineering unit used and the SSME component mnemonic.

An interactive, menu driven program has been written to process the data and extract the features. In Fig. 13 a beginning MENU of the program is shown. Various types of operations are available by choosing the appropriate code. these operations include both recursuve and non-recursive filters, data compression, Logical Operations, FFT, Look-Up-Tables etc.

Fig. 13 Operations MENU

The first step is to read the raw data for a ssr by choosing the appropriate PID#. In Fig. 14 the data for PID#367, for the entire duration of 320 to 392 seconds is shown

FILES: 1=FOR001.DAT:486

Fig. 14. MCC H. G. INJ PR, PID #367, RUN 901-364

From the above figure it is clear that the data has some structure in the form of some distinct features, however, the noise level is fairly high to mask them. the first step we have taken is to reduce the 'observational sampling rate' through moving average. This is done in the following three steps;

<-- Y XIV-17

1. Select a window size N = 0, 1, 2 . . . .

Let M = 2N + 1

2. Form signal averages  $\underline{S}_{k}$  from the raw signal  $S_{i}$ 

$$\underline{S}_{k} = \sum S_{i}/M$$
;

where k = N+1, 2N+1, 3N+1, ... 2rN+1, ... and

i = k-N, k-N+1, ...k+N

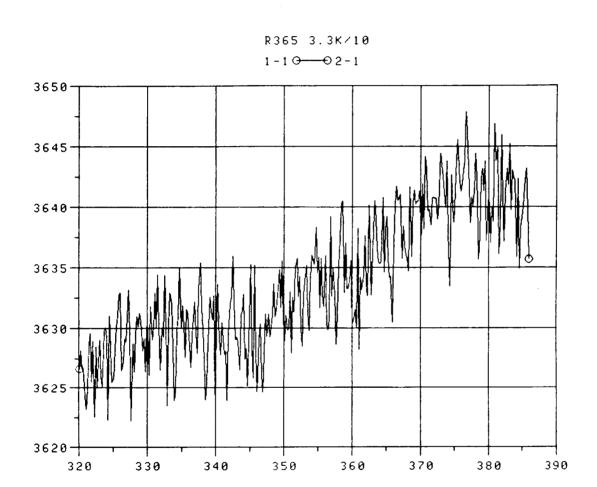

3. Replace the original signal  $S_i$  by  $\underline{S}_k$ , the sampling rate in the new signal,  $\underline{S}_k$ , is reduced by a factor of N.

In Fig. 15 the sampling rate of the data in Fig. 14 has been reduced by N=9, or compressed by a factor of 9. the program allows an interactive choice of N. the data in Fig. 15 still seems to have some noise which can be removed by various filtering techniques. As an illustration Fig. 16 shows the result of applying a non-recursive to the data of Fig. 15.

the data in Fig. 16 seems to have two distinct features, namely, a predominant frequency and a 'drifting background'. To separate these two components one can determine local averages over an interval larger than the hi-freq. wavelength as shown by the background line in Fig. 17. from this one can determine the zero-crossing points. A smooth curve can be fitted to these points to determine the background, as shown in Fig. 18.

the background level, as found in Fig. 18 can now be subtracted from Fig.16 to give the hi-freq. component of the signal, as shown in Fig. 19. This signal can further be 'smoothed' to yield a 'cleaner' hi-freq. signal, as shown in Fig. 20.

FILES: 1=F0R001.DAT:497

the original signal of Fig. 14 can now be said to have two distinct features as represented by Figs. 18 & 20. the former is a slow drift with with plateaus, whereas the latter is a high frequency jitter, which, if needed, can be Fourier analysed. This drift and the high frequency can now be taken as features for representation in the feature space as discussed earlier.

the above steps can now be repeated for the other sensors. the accumulation of all such ssrs and their features can be put in a single time-feature file to construct trajectories. the present computer facilities, with the limited memory allocation and the lack of on-line graphics, did not allow such implementation. A demonstration of this, however, was realised off-line at UAH facility and presented as a video film at MSFC.

From this study, the design of a comprehensive system to analyse the SSME ground test data has been made, the system should consist of;

- 1. A double density (6250/1600 bpi) tape drive interfaced to the host VAX/VMS environment.
- 2. An on-lne RGB graphics display.
- 3. At least 20M disk memory.
- 4. A graphics kernel with hooks to application environment.
- 5. A two tiered version of software for interactive development and macro oriented operation.

#### Conclusions

- -- A feature space description of the SSME ground test data has been realised.
- -- An interactive program has been written to extract features from the ground test data.
- -- Techniques of pattern recognition have been identified to measure the deviations from the normal runs
- -- A design of a more comprehensive program has been made to;
  - A. Survey a large number of normal runs (about 50), and
  - B. Survey all the failed runs (27) and compare them with the above.
- -- Considering that an overall comprehensive review of neither the normal nor the failed runs exists it is highly recommended that an analysis environment of the type discussed above, be implemented.
